METHOD AND SYSTEM FOR THE AUTOMATIC SEGMENTATION OF AN AUDIO STREAM INTO SEMANTIC OR SYNTACTIC UNITS

A digitized speech signal (600) is input to an FO (fundamental frequency) processor that computes (610) a continuous FO data from the speech signal. By the criterion voicing state transition (voiced/unvoiced transitions) the speech signal is presegmented (620) into segments. For each segment (630) it is evaluated (640) whether FO is defined or not defined i.e. whether FO is ON or OFF. In case of FO = OFF a candidate segment boundary is assumed as described above and, starting from that boundary, prosodic features are computed (650). The feature values are input into a classification tree and each candidate segment is classified thereby revealing, as a result, the existence or non-existence of a semantic or syntactic speech unit.
